20 **ABSTRACT**

21 Human Respiratory Syncytial Virus (RSV), for which neither a vaccine nor  
22 an effective therapeutic treatment is currently available, is the leading cause of  
23 severe lower respiratory tract infections in children. Interferon stimulated gene 15  
24 (ISG15) is an ubiquitin-like protein that is highly increased during viral infections  
25 and has been reported to play an antiviral or a proviral activity, depending on the  
26 virus. Previous studies from our laboratory demonstrated a strong ISG15 up-  
27 regulation during RSV infection *in vitro*. In this study, an in depth analysis of the  
28 role of ISG15 in RSV infection is presented. ISG15 overexpression and siRNA  
29 silencing experiments, along with ISG15 knockout cells (ISG15<sup>-/-</sup>) revealed an anti-  
30 RSV effect of this molecule. Conjugation inhibition assays demonstrated that  
31 ISG15 exerts its antiviral activity via protein ISGylation. This antiviral activity  
32 requires high levels of ISG15 to be present in the cells before RSV infection.  
33 Finally, ISG15 is also up-regulated in human respiratory pseudo-stratified epithelia  
34 and in nasopharyngeal washes from infants infected with RSV, pointing to a  
35 possible antiviral role of this molecule *in vivo*. These results advance our  
36 understanding of the innate immune response elicited by RSV and open new  
37 possibilities to control infections by this virus.

38

39 **IMPORTANCE**

40 At present no vaccine or effective treatment against human respiratory  
41 syncytial virus (RSV) is available. This study shows that interferon-stimulated gene  
42 15 (ISG15) lowers RSV growth through protein ISGylation. In addition, ISG15

43 accumulation highly correlates with RSV load in nasopharyngeal washes from  
44 children, indicating that ISG15 may also have an antiviral role *in vivo*. These results  
45 improve our understanding of the innate immune response against RSV and  
46 identify ISG15 as a potential target for virus control.

47

## 48 INTRODUCTION

49 *Human Respiratory Syncytial Virus* (RSV) is the prototype of the *Pneumovirus*  
50 genus of the *Pneumovirinae* subfamily within the *Paramyxoviridae* family. It is an  
51 enveloped, single-stranded negative sense RNA virus whose genome of 15.2 kb  
52 contains 10 genes encoding a total of 11 proteins (1). These are: Three  
53 glycoproteins (F, G, SH) inserted in the viral envelope; four proteins (N, P, L and  
54 M2-1) associated to the ribonucleoprotein and which are required for RNA  
55 synthesis; an additional protein (M) which forms a protein shell underneath the viral  
56 membrane, and three nonstructural proteins, two of them implicated in modulating  
57 the host innate response to infection (NS1 and NS2) and the other (M2-2) involved  
58 in regulating the switch from RNA transcription to RNA replication (1, 2).

59 RSV is a leading cause of severe pediatric lower respiratory tract infections but  
60 also a significant cause of morbidity and mortality in the elderly and  
61 immunocompromised individuals (3). Symptoms vary from those of a common cold  
62 to bronchiolitis and pneumonia in serious cases (4). The mortality associated to  
63 acute lower respiratory RSV infections in children under the age of five is estimated  
64 to be 66,000-199,000 deaths per year worldwide (5).

65 The host response to RSV infection begins in the epithelial cells of the airways,  
66 where virus replication preferentially occurs. Cytokines such as type I interferons  
67 (IFN- $\alpha$  and IFN- $\beta$ ) are one of the first lines of defense against viral infections and  
68 stimulate the expression of a wide range of genes termed interferon-stimulated  
69 genes (ISGs) involved in the antiviral response (6). Many ISGs can also be  
70 induced by dsRNA or viruses in an IFN-independent manner (7, 8).

71 RSV has been regarded as a poor IFN inducer as well as a poor responder to  
72 IFN (9-12). In fact, NS1 and NS2 proteins inhibit both IFN production and signaling  
73 (13-19). Infected cells, however, express high levels of ISGs, including ISG15 (20).  
74 ISG15 is an ubiquitin-like protein encoded by the interferon-stimulated gene 15.  
75 Similarly to ubiquitination, ISG15 is conjugated to target proteins through a  
76 conserved C-terminal Gly-Gly motif in a process termed ISGylation (21, 22). This  
77 process is conducted through a sequential reaction catalyzed by E1-activating, E2-  
78 conjugating and E3-ligase enzymes which are also induced by type I IFN (23).  
79 UbE1L is the only described E1 enzyme for ISG15 while Ubch8 and HERC5 are  
80 the predominant E2 and E3 enzymes respectively (24-28). ISG15 can be removed  
81 from its target proteins by the ubiquitin-specific protease 18 (USP18), making the  
82 ISGylation process reversible (29, 30). Once ISG15 is conjugated to one of more  
83 than 300 target proteins described (31), it causes either a gain or a loss of function  
84 (23). Interestingly, ISGylation has been described as a co-translational process of  
85 both cellular and pathogen encoded proteins with little specificity (31). In addition to  
86 its conjugated form, free unconjugated ISG15 is present intracellularly and it is also  
87 released to the extracellular space (32, 33). Although the mechanism responsible  
88 for the ISG15 antiviral activity is not fully understood, various studies have reported  
89 an essential role of both conjugated and unconjugated ISG15 in the antiviral  
90 response (34-41). A proviral effect, however, has been described in some cases  
91 (42-44). In contrast, viruses have evolved mechanisms to counteract ISG15  
92 antiviral role; for instance, vaccinia virus E3 protein and influenza B NS1 protein  
93 bind ISG15 antagonizing its activity (24, 45).

94           Despite intensive research, neither a vaccine nor an effective antiviral  
95 therapy against RSV is currently available. A better understanding of the complex  
96 interactions between the virus and the host responses that counteract virus  
97 infection is therefore of great importance (46, 47). While the role of ISG15 in RSV  
98 infection has not been investigated, previous studies from our laboratory  
99 demonstrated a strong induction of this gene as a result of RSV infection in A549  
100 cells (20). In order to determine whether ISG15 may play a role in the innate  
101 immune response elicited by RSV, we characterized ISG15 expression and  
102 ISGylation during RSV infection. Experiments of overexpression of both wild-type  
103 and conjugation-deficient ISG15, silencing of ISG15, UbE1L or USP18 and  
104 infection of ISG15<sup>-/-</sup> cells demonstrated an antiviral activity of conjugated ISG15  
105 against RSV. In addition, a strong correlation was found between viral infection and  
106 expression of ISG15 in relevant models of infection both *in vitro* and *in vivo*.  
107

## 108 **MATERIAL AND METHODS**

### 109 **Cells and virus.**

110 Human lung carcinoma cells (A549) and human carcinoma HeLa derived  
111 cells (HEp-2) were maintained in Dulbecco's modified Eagle's medium (DMEM,  
112 Lonza) supplemented with 10% fetal bovine serum (FBS, Biowest), 4 mM L-  
113 Glutamine (Lonza), 100 U/ml penicillin (Lonza) and 100 U/ml streptomycin (Lonza).  
114 All cells were incubated at 37°C in a 5% CO<sub>2</sub> atmosphere. To generate viral stocks,  
115 the RSV Long strain was propagated in HEp-2 cells and purified from clarified  
116 culture supernatants by polyethylene glycol precipitation and centrifugation in a  
117 discontinuous sucrose gradient as previously described (20, 48).

### 118 **Viral infections and plaque assays.**

119 A549 subconfluent monolayers were infected with RSV at a multiplicity of  
120 infection (MOI) of 3 plaque-forming units (pfu) per cell (as indicated in the figure  
121 legend, MOI of 30 or 0.3 was also used in some experiments). Cells were  
122 incubated with the viral inoculum in DMEM 2% FBS (DMEM2) for 90 minutes at  
123 37°C. After this time, the inoculum was removed and fresh DMEM2 was added.  
124 Cell supernatants for viral titration and cell pellets for RNA and protein extraction  
125 were collected at different hours post-infection (hpi). For cell-associated virus, cells  
126 were washed with DMEM2, scrapped off in fresh DMEM2, disaggregated by  
127 thoroughly pipetting and brief sonication in an ultrasonic bath, and virus titrated in  
128 the clarified supernatant.

129 To determine the viral titer, HEp-2 cell monolayers were incubated with  
130 serial dilutions of the cell supernatants for 90 minutes at 37°C and then overlaid  
131 with 0.7% agarose in DMEM2. Five days post-infection (dpi), the cell monolayers

132 were fixed with 4% formaldehyde in PBS followed by methanol permeabilization.  
133 Cells were incubated with a mixture of monoclonal antibodies against RSV (20  
134 and plaques were visualized using an anti-mouse IgG horseradish peroxidase  
135 linked whole antibody (Abcam) and 3-amino-9-ethylcarbazole (AEC, Sigma).

#### 136 **Quantitative RT-PCR and western blots.**

137 Total RNA from mock-infected or infected cells was purified with the RNeasy  
138 Mini Kit (Qiagen) and was reverse transcribed with the High-Capacity cDNA  
139 Archive Kit (Applied Biosystems) following the manufacturer's instructions. Gene  
140 expression was measured by quantitative RT-PCR (qRT-PCR) with a Step One  
141 instrument (Applied Biosystems) and performed in triplicate following the  
142 manufacturer's protocols. PCR primers and TaqMan MGB probes (FAM dye-  
143 labeled) for the following genes were used:  $\beta$ -actin (Hs99999903\_m1), ISG15  
144 (Hs00192713\_m1), UbE1L (Hs00163295\_m1), USP18 (Hs00276441\_m1), IFIT1  
145 (Hs00356631\_g1), RIG-I (Hs00204833\_m1) and RSV nucleoprotein (forward  
146 primer: 5'CATGATTCTCCTGATTGTGGGATGA3', reverse primer:  
147 5'TCACGGCTGTAAGACCAGATCTAT3', probe: 5'CCCCTGCTGCCAATTT3')  
148 (Applied Biosystems). Gene expression was normalized to the  $\beta$ -actin expression  
149 and the comparative CT ( $\Delta\Delta$ CT) method was used for relative quantifications.

150 Protein expression was analyzed by western blot. Cell pellets were  
151 resuspended in sodium-deoxycholate lysis buffer and protein concentration was  
152 determined using a Bradford protein assay (Biorad). A total of 10 $\mu$ g of each protein  
153 sample was separated in 10% or 15% SDS-PAGE gels and subsequently  
154 transferred to an immobilon-P membrane (Milipore). Primary antibodies for

155 detection of the following proteins were used: ISG15 (H150sc-50366, Santa Cruz),  
156  $\beta$ -actin (8224-100, Abcam), RSV phosphoprotein (67P), RSV G glycoprotein  
157 (021/1G), RSV fusion protein (476-510) and RSV nucleoprotein (79N) (49, 50).  
158 Horseradish peroxidase-linked anti-rabbit or anti-mouse Ig (Abcam) were used as  
159 secondary antibodies. Proteins were visualized by chemiluminescence using Clarity  
160 Western ECL Substrate (Biorad) in a Gel Logic 1500 Imaging System instrument  
161 (Kodak). The intensity of the protein bands was quantified by using Image J  
162 software (<http://rsb.info.nih.gov/ij/index.html>) and standardized against  $\beta$ -actin.

### 163 **ISG15 overexpression assays.**

164 Total RNA from A549 RSV-infected cells was reverse transcribed with the  
165 High-Capacity cDNA Archive Kit using an oligo-dT primer (Applied Biosystems)  
166 and ISG15 was amplified using the following primers: forward  
167 (5'AAAAGCGGCCGCGGTGCTGCCTGCCGAAG3') and reverse  
168 (5'AAAAGCGGCCGCTCTTTACAACAGCCTTTATTTCCG3'). The PCR product  
169 was cloned into the mammalian vector pCMV6-Neo (Origene) and the resulting  
170 plasmid pCMV6-Neo-ISG15 was sequenced in order to verify that the ISG15  
171 sequence was correct. Synthesis of the non-conjugative ISG15 plasmid pCMV6-  
172 Neo-ISG15-LRAA from pCMV6-Neo-ISG15 was performed by directed  
173 mutagenesis using the Phusion Site-directed Mutagenesis kit (Thermo Scientific)  
174 following the manufacturer's instructions with the following primers: forward  
175 (5'CCTGCGGGCAGCCGGCACAGAGCCTGGCGGGCGGAGC3') and reverse  
176 (5'GGCTGCCCGCAGGCGCAGATTCATGAACACGGT3').

177 For overexpression assays,  $5 \times 10^4$  A549 cells were plated in each well of a  
178 12-well plate and incubated for 60 hours before transfection. Cells were then  
179 transfected with 1  $\mu$ g of purified plasmid (EndoFree Plasmid Maxi Kit, Qiagen) and  
180 4 $\mu$ l of Lipofectamine 2000 (Invitrogen) per well. Twenty-four hours after  
181 transfection, the cells were infected with RSV at a MOI of 3. Cell supernatants for  
182 viral titration and cell pellets for RNA and protein extraction were collected at  
183 different hpi.

#### 184 **siRNA silencing.**

185 A549 cells were plated 24 hours before transfection at a density of  $5 \times 10^4$   
186 cells per well in 24-well plates. Cells were transfected with 6 pmol of control small  
187 interfering RNAs (siRNAs) or specific siRNAs against ISG15, UbE1L or USP18  
188 (Ambion) and 1  $\mu$ l of Lipofectamine RNAiMAX reagent (Invitrogen) per well.  
189 Twenty-four hours after transfection, cells were infected with RSV at a MOI of 3. In  
190 the case of IFN- $\beta$  treatment, culture medium was replaced four hours after  
191 transfection with fresh medium containing 500 U/ml of IFN- $\beta$  (pbl assay science)  
192 and maintained during the whole infection period. Cell supernatants for viral  
193 titration and cell pellets for RNA and protein extraction were harvested at different  
194 hpi, as indicated in the figure legends.

#### 195 **ISG15 knockout A549 cells.**

196 Two clones of ISG15 knockout (ISG15<sup>-/-</sup>) A549 cells were generated using  
197 the Transcription Activator-Like Effector Nucleases (TALENs) technology. This  
198 technology allows generating knockout cells by using sequence-specific DNA-

199 cleaving enzymes against specific target genes (51). Cells were transfected as  
200 described above with the purified plasmids Human-H36698\_TALEN\_L1 and  
201 Human-H36698\_TALEN\_R1 (Talen Library Resource, Seoul National University).  
202 Three days after transfection, cells were trypsinized and cloned by limiting dilution  
203 in 96-well plates at a density of one cell per well. Single cell clones were selected  
204 and expanded to generate stocks. Cell DNA was extracted with the Cyclo-Prep  
205 Genomic DNA Purification kit (Amresco) following the manufacturer's instructions.  
206 Screening for ISG15<sup>-/-</sup> clones was conducted by PCR amplification and DNA  
207 sequencing using the following primers: forward  
208 (5'GAGCAGCTCCATGTCGGTGTC3') and reverse  
209 (5'ACACGGTGCTCAGGGGCTTG3'). ISG15<sup>-/-</sup> clones were confirmed by western  
210 blot using an ISG15 specific antibody. All selected clones were grown, cloned a  
211 second time by limiting dilution, and checked again by sequencing and western  
212 blot to ensure that they did not express ISG15. Two wild-type clones that  
213 underwent the same process of transfection and cloning were selected as controls.

214 Virus growth was monitored in wild-type and ISG15<sup>-/-</sup> cells treated or not with  
215 500 U/ml of IFN-β 20 hours before infection. Cell supernatants were collected for  
216 virus titration at 48 hpi.

### 217 **Pseudo-stratified epithelia.**

218 Human lung tissue samples were obtained from patients who underwent  
219 surgery for lung carcinoma. Experiments were approved by the local ethics  
220 committee and informed consent was obtained. Human bronchial epithelial cells  
221 were obtained from normal tissue and differentiated to multilayered epithelia as

222 previously described (52). Samples were mock-infected or infected with RSV at  
223  $7 \times 10^6$  pfu/cm<sup>2</sup> and cells were collected at different dpi, RNA was extracted with  
224 TRIZOL reagent (Invitrogen) and further purified and reverse-transcribed as  
225 described above. Samples were analyzed by qRT-PCR using specific RSV  
226 nucleoprotein and ISG15 probes.

### 227 **Nasopharyngeal wash samples.**

228 Nasopharyngeal wash samples from 19 children up to 24 months old  
229 infected with RSV were harvested at admission and discharge by instillation of 2.5  
230 ml of a an isotonic saline solution into each nostril (NaCl 0.9%) as described  
231 elsewhere (53). In all cases, an informed consent was requested from the parents  
232 or legal guardians prior to the inclusion of the child in the study. Approval of the  
233 Committee for Ethics in Clinical Research of the “Hospital Clínico Universitario” in  
234 Valladolid (Spain) was obtained prior to the beginning of recruitment. Total RNA  
235 was extracted, reverse transcribed and gene expression quantified as described  
236 above.

237

## 238 RESULTS

### 239 RSV infection induces ISG15 expression and protein ISGylation.

240 To investigate if ISG15 expression is up-regulated after *in vitro* RSV  
241 infection, A549 cells were infected and the levels of ISG15 and RSV nucleoprotein  
242 RNAs were analyzed by qRT-PCR at different hpi. Fig. 1A shows a large increase  
243 of ISG15 RNA in RSV infected A549 cells in a time-dependent manner. The  
244 increase started between 6 to 16 hpi, reaching maximum level 48 hpi. ISG15 RNA  
245 increase showed a delay of 4-5 hours with respect to RSV nucleoprotein RNA (Fig.  
246 1A). A high correlation between ISG15 and nucleoprotein RNA expression was  
247 observed ( $R^2=0.97$ ,  $P<0.0001$ ) (Fig. 1B).

248 To confirm the above results and to determine whether the RNA levels of  
249 ISG15 and RSV nucleoprotein were translated to the protein levels, samples from  
250 a parallel infection were analyzed by western blot at various hpi. RSV  
251 nucleoprotein started to be detected 4 hpi (Fig. 1C) and increased continuously  
252 until 48 hpi. RSV infected A549 cells expressed large amounts of both free ISG15  
253 and ISG15 conjugates. Accumulation of free ISG15 was time-dependent,  
254 becoming apparent 16 hpi, while the increase of ISG15 conjugates was not evident  
255 until 30-36 hpi. As described for RNAs, ISG15 protein increase had a delay of 4-5  
256 hours with respect to the RSV nucleoprotein accumulation (Fig. 1C).

257 Finally, the protein ISGylation patterns obtained after 48 hours of RSV  
258 infection or IFN- $\beta$  stimulation were compared by western blot. The results obtained  
259 revealed common bands being labelled but, additionally, some specific bands

260 appearing only in RSV infected cells or IFN- $\beta$  stimulated cells were apparent (Fig.  
261 1D); i.e., RSV induced ISGylation differs to some extent from that of IFN- $\beta$ .

262 **RSV titer as well as viral proteins and RNA levels are increased in ISG15**  
263 **knockdown or ISG15<sup>-/-</sup> cells stimulated with IFN- $\beta$ .**

264 To analyze whether or not ISG15 has any anti-RSV activity, A549 cells were  
265 transfected with control siRNAs or specific ISG15 siRNAs before being infected  
266 with RSV. No differences were observed in viral titer between ISG15-silenced cells  
267 and control cells (Fig. 2A, -IFN- $\beta$ ). It was hypothesized that this lack of antiviral  
268 effect could be related to the fact that ISG15 expression and formation of ISG15  
269 conjugates is delayed with respect to virus replication (Fig. 1A and 1C). Hence,  
270 ISG15 expression was induced before RSV infection by stimulation of cells with  
271 IFN- $\beta$ . As expected, a decrease in viral titer was observed in IFN- $\beta$  treated cells  
272 when compared with non-treated controls (Fig. 2A). However, an increase of 2.9  
273 times in virus titer was observed in the ISG15-silenced cells with respect to control  
274 cells, indicative of an ISG15 assisted anti-RSV effect (Fig. 2A, +IFN- $\beta$  ).

275 In addition to virus titers, the amount of accumulated viral nucleoprotein and  
276 RNA was quantified at 24 and 48 hpi in control and ISG15-silenced cells previously  
277 stimulated with IFN- $\beta$ . As expected, a clear inhibition of free ISG15 and ISG15  
278 conjugates was observed in ISG15-silenced cells by western blot (Fig. 2B). At the  
279 same time, ISG15-silenced cells showed an increase in the amount of the RSV  
280 nucleoprotein at 24 and 48 hpi compared with control cells (Fig. 2B). Furthermore,

281 a significant increase on the amount of RSV nucleoprotein RNA was observed in  
282 ISG15-silenced cells when compared with control cells at the same hpi (Fig. 2C).

283 To confirm the above results, ISG15<sup>-/-</sup> cells were generated using TALEN  
284 nucleases. Two wild-type and two ISG15<sup>-/-</sup> cell clones were selected for further  
285 studies (Fig. 3A). These four clones, along with the uncloned wild-type cells, were  
286 infected either in the absence or presence of IFN- $\beta$  at a MOI of 3 and viral titers  
287 were determined 48 hours later. As expected, no significant differences were found  
288 among the untreated wild-type or ISG15<sup>-/-</sup> cells. However, in the IFN- $\beta$  treated  
289 cells, a significant increase (from 1.9 to 4.6-fold) in viral titer was found in ISG15<sup>-/-</sup>  
290 cells, compared with wild-type cells (Fig. 3B). Together, these results demonstrate  
291 that ISG15 has an anti-RSV activity in cells previously stimulated with IFN- $\beta$ .

292 When RSV infections were carried out at MOI 30 or 0.3, an increase in virus  
293 titer was also observed in ISG15<sup>-/-</sup> cells previously treated with IFN- $\beta$  (Fig. 3C). The  
294 magnitude of this effect seemed to decrease as MOI increased, suggesting that  
295 ISG15 inhibition was more effective with lower input virus, as otherwise might be  
296 expected for a partial block in virus replication.

297 **ISG15 overexpression before virus infection reduces RSV titer as well as**  
298 **viral proteins and RNA accumulation.**

299 The results from previous sections indicated that the high levels of ISG15  
300 induced by RSV infection had no antiviral effect. However, this antiviral effect was  
301 revealed when ISG15 was overexpressed before virus infection by stimulation of  
302 cells with IFN- $\beta$ . ISG15 might need the collaboration of other proteins induced by

303 IFN- $\beta$  for its antiviral activity or it may be just a matter of the time period at which  
304 ISG15 is expressed in relation to virus infection. To distinguish between these two  
305 possibilities, A549 cells were either transfected with a plasmid overexpressing  
306 ISG15 or with the same empty vector as a negative control, and then infected with  
307 the RSV. Cell supernatants were harvested at 24 and 48 hpi and viral titers  
308 determined by plaque assay. A significant reduction of the viral titer (4.8-fold) was  
309 observed in the ISG15 overexpressing cells when compared with control  
310 transfected cells at 48 hpi (Fig. 4A). Western blot analysis of four viral proteins  
311 revealed decreased accumulation in the ISG15 transfected cells compared with  
312 control cells. This decrease was observed at 24 and 48 hpi, with the most evident  
313 effect at 24 hours (Fig. 4B). In addition, the RSV nucleoprotein RNA was analyzed  
314 by qRT-PCR at the same hpi. The results showed a significant RNA reduction in  
315 the ISG15 overexpressing cells compared to control cells at both 24 and 48 hpi  
316 (Fig. 4C).

317 Therefore, these findings support the conclusions reached with ISG15-  
318 silenced or ISG15<sup>-/-</sup> cells and demonstrated that ISG15 has an anti-RSV activity  
319 when overexpressed before virus infection, either alone or in the context of the  
320 antiviral response induced by IFN- $\beta$ .

### 321 **Antiviral activity of ISG15 against RSV is due to protein ISGylation.**

322 In order to determine if ISG15 accomplishes its antiviral activity against RSV  
323 in a conjugated or unconjugated form, experiments were carried out using three  
324 different approaches:

325 First, since a C-terminal Gly-Gly motif is required for ISG15 conjugation (21,  
326 22), a plasmid was generated by site-directed mutagenesis in which those two  
327 residues were mutated to Ala. This plasmid therefore expresses an ISG15 protein  
328 that cannot be conjugated to target proteins. A549 cells were transfected with the  
329 plasmid expressing either wild-type ISG15, the plasmid expressing non-conjugative  
330 ISG15 or an empty vector. Twenty-four hours later, cells were infected with RSV  
331 and virus titers were measured at 48 hpi. As expected, a significant decrease (3.9-  
332 fold) was found in the viral titer of cells overexpressing wild-type ISG15 when  
333 compared with control cells transfected with the empty vector. However, no  
334 differences were found between these control cells and cells transfected with the  
335 non-conjugative ISG15 plasmid (Fig. 5A). Similar results were obtained after  
336 transfection/infection experiments of ISG15<sup>-/-</sup> cells, demonstrating that their  
337 phenotype can be reconstituted by wild-type ISG15 but not by non-conjugative  
338 ISG15 (Fig. 5B).

339 A second approach to inhibit the formation of ISG15 conjugates was  
340 knocking down the only identified E1 enzyme for ISG15, UbE1L (24). A549 cells  
341 were either transfected with control siRNAs or specific UbE1L siRNAs and then  
342 infected with RSV in either the absence or presence of IFN- $\beta$ . IFN- $\beta$ -stimulated  
343 UbE1L-silenced cells expressed high levels of free ISG15, as did control cells, but  
344 failed to form ISG15 conjugates (Fig. 5C). Besides, similarly to what happened with  
345 ISG15-silenced cells, UbE1L inhibition led to an important increase in the amount  
346 of RSV nucleoprotein at 24 and 48 hpi (Fig. 5C). Also, resembling the results of  
347 infecting ISG15-silenced cells with RSV (Fig. 2A), no differences were found

348 between the UbE1L-silenced cells and control cells in the absence of IFN- $\beta$   
349 stimulation (Fig. 5D, -IFN- $\beta$ ). In contrast, a significant increase (3.9-fold) in viral  
350 titer was observed in the UbE1L-silenced cells and treated with IFN- $\beta$  when  
351 compared with control cells (Fig. 5D, +IFN- $\beta$ ).

352 The third approach consisted in silencing of USP18, an ISG15-specific  
353 deconjugating protease that removes ISG15 from its protein targets (29, 30). As  
354 expected, the results were the opposite of those obtained from UbE1L silencing  
355 experiments: in IFN- $\beta$  treated cells, USP18 silencing increased protein ISGylation,  
356 decreased RSV nucleoprotein accumulation (Fig. 5E) and reduced virus titers (3.3-  
357 fold) (Fig. 5F).

358 Altogether, these data indicate that ISGylation, rather than free ISG15, is  
359 responsible for the anti-RSV activity of this molecule.

360 In addition to its role in protein ISGylation, it has been reported that ISG15  
361 and USP18 act together to counteract IFN- $\alpha/\beta$  signaling (54, 55). Hence, the  
362 expression of IFIT1 and RIG-I (two ISGs) was measured in cells silenced for  
363 ISG15, UbE1L or USP18 that were previously treated with IFN- $\beta$  and then infected  
364 with RSV. As expected, a slight increase in the expression of IFIT1 and RIG-I  
365 mRNA was observed in cells knocked down for ISG15 or USP18, but not for  
366 UbE1L (Fig. 6). Despite having similar effect on IFIT1 and RIG-I expression, ISG15  
367 and USP18 silencing had opposite effect on RSV growth (Fig. 2A and 5F),  
368 indicating that, with regard to RSV inhibition, the effect on protein ISGylation  
369 predominates over the effect on ISGs expression. It cannot be excluded, however,

370 that the overexpression of ISGs may contribute somewhat to reduce RSV titer in  
371 USP18 knocked down cells.

372 **The ISG15 anti-RSV activity affects a post-entry stage of infection before**  
373 **virus release.**

374 Since it has been shown that ISG15 may affect virus entry (56) or release  
375 (34, 37), two experiments were carried out to gain information about the role of  
376 ISG15 in those steps of RSV replication.

377 First, A549 cells were transfected with a plasmid expressing ISG15 or a  
378 control plasmid before being infected with RSV under single infectious cycle  
379 conditions. Then, the accumulation of RSV nucleoprotein RNA was quantified by  
380 qRT-PCR at several hpi. The results showed a significant RNA reduction in the  
381 ISG15 overexpressing cells compared to control cells starting between 8-15 hpi  
382 (Fig. 7A). This result shows that ISG15 restricts RSV growth at a post-entry stage  
383 of infection.

384 In addition, the virus released to the supernatant and the virus associated to  
385 cells was quantified in ISG15- or control-transfected cells. As expected from  
386 previous experiments a more than three-time reduction in virus titer was observed  
387 in the supernatant of ISG15-transfected cells with respect to control-transfected  
388 cells (Fig. 7B, supernatant). Similarly, a significant decrease of more than two-fold  
389 was also observed in virus titers from the cell-associated fraction of ISG15-  
390 transfected cells when compared to the same fraction of control cells (Fig. 7B, cell-

391 associated). This indicates that an ISG15-mediated restriction on RSV infection  
392 occurs before virus release.

393 **ISG15 expression correlates with RSV infection in pseudo-stratified**  
394 **respiratory epithelia and in nasopharyngeal washes from infants.**

395 As a preliminary step to investigate the role of ISG15 in the anti-RSV  
396 response *in vivo*, its expression was analyzed in more relevant models of infection.  
397 Firstly, an *in vitro* model of differentiated pseudo-stratified columnar respiratory  
398 epithelium with ciliated and mucus producing cells that resembles *in vivo*  
399 conditions was used for RSV infection (52). Differentiated cultures from six donors  
400 were infected and viral yield and ISG15 expression were quantified by qRT-PCR at  
401 different dpi. ISG15 levels of infected samples correlated with RSV nucleoprotein  
402 expression in every sample and time post-infection tested. A high positive  
403 correlation ( $R^2=0.77$ ,  $P<0.0001$ ) between viral infection and the ISG15 expression  
404 level was observed (Fig. 8A).

405 Secondly, nasopharyngeal washes from 19 young infants infected with RSV  
406 were obtained at admission and discharge (38 samples in total). After RNA  
407 extraction, RSV nucleoprotein and ISG15 RNA levels were determined by qRT-  
408 PCR. Similarly to the pseudo-stratified epithelia, a high positive correlation  
409 ( $R^2=0.63$ ,  $P=0.0004$ ) between RSV nucleoprotein and ISG15 expression was  
410 observed (Fig. 8B). These data demonstrate that ISG15 is induced by RSV  
411 infection *in vivo* and suggest that ISG15 may play an antiviral role after natural  
412 infection.

## 413 **DISCUSSION**

414 In this study, the antiviral activity of ISG15 against RSV was investigated.  
415 RSV infection of A549 cells induced high levels of both free and conjugated ISG15.  
416 Furthermore, overexpression of ISG15, or pretreatment with IFN- $\beta$  of cells that  
417 were ISG15-silenced or ISG15<sup>-/-</sup>, demonstrated that ISG15 played an important  
418 role as an anti-RSV molecule. The ISG15 antiviral activity required protein  
419 ISGylation as was evidenced by the lack of effect of a non-conjugative form of  
420 ISG15, the inhibition of ISGylation by UBE1L silencing or the increase of ISGylation  
421 by USP18 knockdown. Moreover, a high correlation between RSV infection and  
422 ISG15 expression was established both in a relevant model of infection, such as  
423 human respiratory pseudo-stratified epithelia, and in nasopharyngeal washes from  
424 infected children.

425 Although the antiviral activity of ISG15 has been widely described (57, 58),  
426 the mechanisms through which ISG15 exerts its effects have only been hinted in  
427 some cases. The antiviral activity of ISG15 has been described to occur in the late  
428 stages of the viral cycle of HIV and in Ebola virus infections, where ISG15 inhibits  
429 virus release (34, 37). In contrast, it has been recently described that ISG15  
430 inhibits early steps, such as entry and/or uncoating, of the Murine norovirus life  
431 cycle, although no specific target proteins responsible for these effects have been  
432 identified (56). ISG15 has been claimed to exert its antiviral activity by conjugation  
433 to either viral or cellular proteins. For instance, ISGylation of the NS1 protein of  
434 Influenza A virus reduced its capacity to antagonize the host antiviral response (59,

435 60) and ISG15 conjugation to IRF3 during Sendai virus infection inhibited its  
436 proteasome-mediated degradation, boosting the host antiviral response (61).

437 Our results show that, in order to exert its anti-RSV activity, ISG15 has to  
438 accumulate to high amounts before virus infection. They also indicate that ISG15  
439 carry out its anti-RSV action after virus entry. In addition, ISG15 seems to affect a  
440 stage in the RSV cycle before virus release, since RSV titers decreased in both  
441 released and cell-associated virus following ISG15 overexpression. Given that  
442 ISGylation is ordinarily a co-translational modification (31), it is possible that the  
443 ISG15 anti-RSV activity is mediated by direct ISGylation of viral and/or cellular  
444 proteins essential for virus replication. In this situation, in the first RSV infected  
445 cells, ISG15 would not have an antiviral effect because most viral proteins have  
446 already accumulated to high levels before the ISGylation machinery is triggered. In  
447 cells that acquire an antiviral state before virus infection, such as those stimulated  
448 by interferon, the ISGylation machinery is ready to operate as soon as the virus  
449 enters into the cell. In this case, ISG15 may interfere with RSV replication by  
450 ISGylation of viral or cellular proteins required for RNA replication/transcription,  
451 being P, L, M2-1 and M2-2 obvious protein viral targets which are now under study.  
452 Additionally, or alternatively, binding of certain RSV protein(s) to ISG15 may be  
453 required to antagonize its antiviral effect, as occurs with vaccinia virus E3 or  
454 influenza B NS1 proteins (24, 45). In this case, when ISG15 levels increase in the  
455 first RSV infected cells, the amount of viral proteins has already reached levels  
456 capable of neutralizing ISG15 activity. In contrast, when ISG15 is expressed at  
457 high levels before virus infection, as in cells previously stimulated by IFN- $\beta$ , no viral

458 proteins are present to counteract the ISG15 antiviral effect. The same reasoning  
459 would apply if RSV protein(s) antagonize any of the enzymes involved in  
460 ISGylation, instead of ISG15 directly.

461 It has been shown that USP18 regulates negatively the IFN- $\alpha/\beta$  signaling  
462 independently of its ISG15 isopeptidase activity (54) (Fig. 9). This regulation  
463 required ISG15 to stabilize USP18, a process that was ISGylation-independent  
464 since it was mediated by non-conjugating ISG15 and it was not affected by UbE1L  
465 silencing (55). According to this, the lack of ISG15 would destabilize USP18  
466 leading to an increased response to IFN type I and viral resistance (55) (Fig. 9). In  
467 line with this, we have observed a modest increase in the expression of the  
468 interferon stimulated genes IFIT1 and RIG-I in both ISG15 and USP18 silenced  
469 cells treated with IFN- $\beta$  and infected with RSV (Fig. 6). By contrast, UbE1L  
470 silencing reduced the expression of those genes (Fig. 6), perhaps by increasing  
471 free ISG15 levels due to impaired ISGylation. Our results, however, demonstrated  
472 that the anti-RSV activity of ISG15 in A549 cells was ISGylation-dependent and  
473 largely independent of its effect on USP18 stabilization because: i) non-conjugating  
474 ISG15 is able to stabilize USP18 (55), but it does not have any effect on RSV  
475 replication (Fig. 5A and 5B); ii) UbE1L silencing had no effect on USP18  
476 stabilization (55), but it increased virus titers in IFN- $\beta$  treated cells (Fig 5D); iii)  
477 while ISG15 and UbE1L silencing had opposite effects on the expression of IFIT1  
478 and RIG-I (Fig. 6), both increased RSV replication (Fig. 2A and 5D); and iv) ISG15  
479 or USP18 silencing in IFN- $\beta$  treated cells had opposite effects on RSV titers (Fig.  
480 2A and 5F), consistent with the ISG15 isopeptidase activity of USP18 but contrary

481 to the results expected from a joint action of ISG15 and USP18, such as that  
482 observed in the IFN response regulation (Fig. 9). Our results agree with the  
483 recently reported observations showing that selective inactivation of the USP18  
484 isopeptidase activity in knock-in mice enhanced protein ISGylation and resistance  
485 against vaccinia and influenza B viruses without inducing any obvious changes in  
486 the IFN signaling pathway (62).

487         The positive correlation observed in this study between RSV infection and  
488 ISG15 expression in human pseudo-stratified epithelia and in nasopharyngeal  
489 washes from infected children point to a role in RSV infections *in vivo*. Virus  
490 replication in infected cells generates products that act as pathogen associated  
491 molecular patterns (PAMPs), which directly trigger intracellular innate pathways  
492 leading to the expression of ISG15 and other antiviral and proinflammatory genes  
493 that initiate the immune response (7, 8). In this setting, uninfected respiratory  
494 epithelial cells might acquire an antiviral status, which includes high levels of  
495 ISG15, through stimulation by IFN secreted from neighboring infected cells and/or  
496 immune cells attracted to the site of infection in the respiratory tract (63, 64).  
497 Subsequent infection of those cells by RSV would be impaired by the previously  
498 acquired antiviral state. In this scenario, ISG15 would play an important role to  
499 hinder RSV dissemination. In addition, overexpression of ISG15 during RSV  
500 infection may contribute to control the excessive inflammation by stabilizing USP18  
501 (55). The role of ISG15 in viral infections *in vivo* requires, however, further  
502 investigation since it seems to be complex and multifaceted, as demonstrated by  
503 conflicting results from ISG15-deficient human and mice (55, 57), as well as by the

504 identification of a novel ISG15 conjugation-dependent mechanism by which mice  
505 are protected against influenza A and Sendai virus infection without obvious effect  
506 on virus replication and immune response (65), which contrast with the observation  
507 that protein ISGylation restricted virus replication and enhanced resistance to  
508 vaccinia virus and influenza B virus in mice (62).

509         The close correlation between RSV load and ISG15 expression in infants  
510 and the fact that ISG15 is secreted to human fluids, where it can be quantified,  
511 raises the possibility to use this molecule to monitor RSV-induced inflammation  
512 (66). Related to this, it is important to stress that ISG15 levels decreased between  
513 admission and discharge, for every single infant, reflecting the reduction in virus  
514 load and inflammation (data not shown).

515         In conclusion, we have described for the first time that ISG15 has a  
516 conjugation-dependent antiviral activity against RSV. In addition, data from  
517 nasopharyngeal washes from infants infected with RSV suggest that ISG15 may  
518 play an important role in RSV infection *in vivo*. Therefore, although further research  
519 is required to elucidate the mechanisms of ISG15 interference with RSV, this study  
520 enhances our understanding of the innate immune response against RSV and  
521 identifies ISG15 as a potential target for virus control.

## 522         **ACKNOWLEDGMENTS**

523         This work was supported by grant PI11/00590 from Fondo de Investigación  
524         Sanitaria to IM.

525         We are grateful to Dr.Vanesa Matías and Dr. María Pino for patient enrollment.

712 **FIGURE LEGENDS**

713 **Figure 1. RSV infection of A549 cells enhances ISG15 expression and protein**

714 **ISGylation.** (A) A549 cells were infected with RSV at a MOI of 3 and harvested at  
715 the indicated hpi. RSV nucleoprotein and ISG15 RNAs were quantified by qRT-  
716 PCR. Data represent the fold increase of ISG15 RNA in infected cells compared  
717 with mock infected cells, and the fold increase of RSV nucleoprotein RNA with  
718 respect to zero hpi. (B) Linear regression plot of RSV nucleoprotein and ISG15  
719 RNA expression data from graphic A. (C) A549 cells were infected with RSV and  
720 harvested at the indicated hpi. Protein accumulation was analyzed by western blot  
721 using anti ISG15 and anti RSV nucleoprotein specific antibodies. Normalization  
722 was carried out using an anti  $\beta$ -actin antibody. (D) Western blot comparing protein  
723 ISGylation patterns induced by interferon- $\beta$  (500 U/ml) or RSV infection after 48  
724 hours. Arrows show treatment-specific ISGylated proteins.

725 **Figure 2. ISG15 downregulation in IFN- $\beta$  stimulated cells increases viral titer**

726 **and viral protein and RNA levels.** (A) A549 cells were transfected with either  
727 control siRNAs or ISG15 siRNAs and infected twenty four hours later at a MOI of 3.  
728 In the case of IFN- $\beta$  treatment, culture medium was replaced four hours after  
729 transfection with fresh medium containing 500 U/ml of IFN- $\beta$  and maintained during  
730 the whole infection period. Cell supernatants were harvested at 48 hpi and virus  
731 titer was determined by plaque assays. (B) Protein extracts from IFN- $\beta$ -treated  
732 RSV-infected cells were collected 24 or 48 hpi and analyzed by western blot using  
733 anti ISG15 and anti RSV nucleoprotein specific antibodies. Proteins were

734 quantified and normalization was carried out using an anti  $\beta$ -actin antibody. (C)  
735 IFN- $\beta$  treated cells were either transfected with control siRNAs or ISG15 siRNAs  
736 and then infected with RSV. RSV nucleoprotein RNA was quantified by qRT-PCR  
737 at the indicated hpi in ISG15 silenced cells and represented as a percentage of the  
738 nucleoprotein RNA expressed in cells transfected with a control siRNA (100%).  
739 Data from (A) and (C) represent the mean and standard deviation from at least  
740 three independent experiments. Comparisons between conditions were done using  
741 the t test. \*  $P < 0.05$ ; \*\*  $P < 0.01$ .

742 **Figure 3. ISG15 knockout in IFN- $\beta$  stimulated cells leads to an increase in**  
743 **viral titer.** (A) Two ISG15-knockout A549 cell lines (ISG15<sup>-/-</sup>) (lanes 4 and 5) were  
744 generated by using TALENs nucleases, and ISG15 expression was checked by  
745 western blot using specific antibodies. Uncloned wild type cells (lane 1) and two  
746 wild type cell clones (lanes 2 and 3) were included as controls. (B) ISG15 wild type  
747 cells and ISG15<sup>-/-</sup> cells were either left untreated or treated with IFN- $\beta$  prior to RSV  
748 infection at MOI of 3. (C) Similar experiments were carried out at MOI of 0.3 and 30  
749 in clones #3 (WT) and #5 (ISG15<sup>-/-</sup>). Cell supernatants were harvested 48 hpi (MOI  
750 of 3 and 30) or 72 hpi (MOI of 0.3) and virus titers determined by plaque assays.  
751 Data represent the mean and standard deviation from three independent  
752 experiments. Comparisons between groups were done by the t test. \*\*  $P < 0.01$ .  
753 Lanes: 1, uncloned wild type cells; 2 and 3, wild type cell clones; 4 and 5, ISG15<sup>-/-</sup>  
754 cell clones.

755 **Figure 4. ISG15 overexpression leads to a decrease in viral titer, proteins and**  
756 **RNA.** A549 cells were either transfected with an ISG15 overexpressing plasmid or

757 a control plasmid and infected at a MOI of 3 with the RSV 24 hours later. (A) Cell  
758 supernatants were collected and virus titer determined by plaque assay at 48 hpi.  
759 (B) Protein extracts from a representative experiment were collected at 24 and 48  
760 hpi and analyzed by western blot using antibodies against ISG15, and the following  
761 RSV proteins: glycoprotein (G), phosphoprotein (P), fusion protein (F) and  
762 nucleoprotein (N). Proteins were quantified and normalization was carried out  
763 using an anti  $\beta$ -actin antibody. 1, Cells transfected with a control plasmid and 2,  
764 cells transfected with the ISG15 plasmid. (C) RSV nucleoprotein RNA was  
765 quantified by qRT-PCR at 24 and 48 hpi. Data represent the percentage of  
766 expression of RSV nucleoprotein RNA in ISG15-transfected cells compared with  
767 cells transfected with a control plasmid (100%). Data from (A) and (C) represent  
768 the mean and standard deviation from four independent experiments. Comparisons  
769 between groups were done by the t test. \*  $P < 0.05$ ; \*\*  $P < 0.01$ .

770 **Figure 5. Antiviral activity of ISG15 against RSV is due to protein ISGylation.**

771 (A) A549 cells were transfected with either a control plasmid, a plasmid  
772 overexpressing ISG15 or a plasmid overexpressing non-conjugative ISG15  
773 (ISG15-LRAA), and infected 24 hours later with RSV at a MOI of 3. Cell  
774 supernatants were collected at 48 hpi and viral titers determined by plaque assay.  
775 (B) ISG15<sup>-/-</sup> A549 cells were transfected, infected and virus titer determined as in  
776 panel A. (C) IFN- $\beta$  treated A549 cells were transfected with either control siRNA or  
777 UbE1L siRNAs and infected 24 hours later with RSV at a MOI of 3. Protein extracts  
778 were collected at 24 and 48 hpi and analyzed by western blot using anti ISG15 and  
779 anti RSV nucleoprotein specific antibodies. Proteins were quantified and

780 normalization was done using an anti  $\beta$ -actin antibody. (D) Untreated and IFN- $\beta$   
781 treated A549 cells were either transfected with control siRNAs or UbE1L siRNAs  
782 prior to RSV infection. Cell supernatants were collected 48 hpi and virus titers  
783 determined by plaque assays. (E) and (F) A549 cells were treated as in panels C  
784 and D but USP18 siRNA, rather than UbE1L siRNA, was used for gene silencing.  
785 In the case of IFN- $\beta$  treatment (C, D, E and F), culture medium was replaced four  
786 hours after transfection with fresh medium containing 500 U/ml of IFN- $\beta$  and  
787 maintained during the whole infection period. Data represent the mean and  
788 standard deviation from at least three independent experiments. Comparisons  
789 between groups were done by the t test. \*  $P < 0.05$ .

790 **Figure 6. ISGs expression in ISG15, UbE1L and USP18 silenced cells.** IFN- $\beta$   
791 treated cells were either transfected with control siRNAs or ISG15 (A), UbE1L (B)  
792 or USP18 siRNAs (C) and then infected with RSV. IFIT1 and RIG-I mRNA was  
793 quantified by qRT-PCR at the indicated hpi in silenced cells and represented as a  
794 percentage of the mRNA expressed in cells transfected with a control siRNA  
795 (100%). Data from (A), (B) and (C) represent the mean and standard deviation  
796 from three independent experiments. Comparisons between conditions were done  
797 using the t test. \*  $P < 0.05$ .

798 **Figure 7. The anti-RSV activity of ISG15 affects a post-entry stage of infection**  
799 **before virus release.** A549 cells were either transfected with an ISG15  
800 overexpressing plasmid or a control plasmid and infected at a MOI of 3 with the  
801 RSV 24 hours later. (A) RSV nucleoprotein RNA was quantified by qRT-PCR at  
802 different hpi. Data represent the percentage of expression of RSV nucleoprotein

803 RNA in ISG15-transfected cells compared with cells transfected with a control  
804 plasmid (100%). (B) RSV titer in the culture supernatant or associated with cells  
805 was determined by plaque assay at 48 hpi. For cell-associated virus, cells were  
806 washed with DMEM2, scrapped off in fresh DMEM2, disaggregated by thoroughly  
807 pipetting and brief sonication in an ultrasonic bath, and virus titrated in the clarified  
808 supernatant. Data from (A) and (B) represent the mean and standard deviation  
809 from three independent experiments. Comparisons between groups were done by  
810 the t test. \*  $P < 0.05$ ; \*\*  $P < 0.01$ .

811 **Figure 8. ISG15 expression correlates with RSV infection *in vitro* and *in vivo*.**

812 (A) Pseudo-stratified epithelia were generated *in vitro* from lung explant of six  
813 donors and either mock-infected or infected with RSV for two and four days (five  
814 individuals) or three days (one individual). RNA was extracted and ISG15 and RSV  
815 nucleoprotein RNA was quantified by qRT-PCR. A linear regression plot of RSV  
816 nucleoprotein against ISG15 RNA levels in each condition is represented. RSV  
817 nucleoprotein fold induction was obtained by comparison to the donor with the  
818 lowest value of expression, and ISG15 fold induction was calculated relative to  
819 mock-infected cells. (B) Nasopharyngeal wash samples from 19 children infected  
820 with RSV were collected at admission (open circles) and discharge (solid circles)  
821 (38 samples in total) and RNA was extracted and quantified by qRT-PCR. A linear  
822 regression plot of RSV nucleoprotein against ISG15 RNA levels in each sample is  
823 represented. RSV nucleoprotein and ISG15 fold induction were relative to an  
824 external control (a dilution of mRNA from A549 cells infected with RSV).

825 **Figure 9. Intracellular ISG15 conjugation-dependent and independent**  
826 **mechanisms of action.** IFN- $\alpha/\beta$  stimulates the expression of a wide range of  
827 genes termed interferon-stimulated genes (ISGs) involved in the antiviral response.  
828 ISG15 is one of those genes that conjugates to target proteins through a three-step  
829 enzymatic process termed ISGylation, for which the E-1 activating enzyme UbE1L  
830 is required. This process is reversed by the ubiquitin-specific isopeptidase USP18.  
831 In addition, free ISG15 stabilizes USP18 to compete with JAK1 for binding to the  
832 IFNAR2, thereby negatively regulating the IFN- $\alpha/\beta$  signaling in an isopeptidase-  
833 independent manner. The impact of these mechanisms on RSV replication is  
834 discussed in the text.
